Peripheral Nerve Regeneration-Ana Colette Maurice 2017-03-01 Peripheral nerve injuries are a high-incidence clinical problem that greatly affects patients’ quality of life. Despite continuous improvement of microsurgical techniques, peripheral nerve repair still stands as one of the most challenging tasks in neurosurgery, as the complex anatomy of peripheral nerves and their complex regeneration process represent a real challenge. The development of surgical techniques and the clinical application of innovative therapies have been intensively studied worldwide. Direct nerve repair with epineural-to-end-to-end sutures is still the gold standard treatment for severe nerve injuries but only in cases where well-vascularized tenon-free coaptation can be achieved. When peripheral nerve injury origination significantly gaps between the nerve stumps, nerve autografts and allografts are employed. These techniques have been used for successful results, but the clinical gap can also be bridged using several alternative techniques to stimulate-optimizing clinical outcome. Nerve conduit tailoring involving reaching ideal wall pores, using extruding techniques in their fabrication, surface coating with growth factors, and the use of biological collagens and other collagen substitutes employed such as the filling with hydrogels, inner surface modification, topographical design, and the introduction of neurotrophic factors, antioxidants, and other pharmacological agents. A comprehensive state of the art of surgical techniques, tissue-engineered nerve graft scaffold, and their application in clinical settings. Recent advances in peripheral nerve repair and future perspectives will be discussed, including surgeons’ and researchers’ own large experiences in this field of knowledge.
